Week 3 Development Reflection Report

FocusDay - Study Reminder App

Student Name	Shen Junye
Module	INFT2051 Mobile App Programming

1. App Overview

This week I continued developing my mobile app called FocusDay. The purpose of this app is to help students organise study tasks, manage time across different dates, and track their progress in a simple way. The app is designed for students who often need a clear daily study plan and quick reminders of what they need to complete.

2. Development Progress

At the start of development, the app only supported a basic daily schedule page with limited interaction. After further testing, I realised that this design was not convenient for real users. A student should not need to move day by day only to check a task in another week or month. Because of this, I improved the date navigation by adding a DatePicker and quick access buttons for Today and Tomorrow. This change made the app faster and more practical to use.

The app now includes several connected pages: a Daily Schedule page, an Add Study Task page, a Task Details page, and a Reminder Settings page. Users can add tasks, view task details, edit existing tasks, delete tasks, and mark tasks as completed. This structure is much closer to a real mobile planning app instead of a simple classroom prototype.

3. User Experience Improvements

One of the most important improvements was making the task list easier to understand visually. When a task is completed, it now shows a tick symbol, the text becomes grey, and the task name has a strikethrough effect. This gives the user immediate feedback and makes the progress of the day easier to recognise at a glance.

I also added edit functionality because students often need to change a task after creating it. In real use, a user may change the study date, time, category, or notes. Without an edit function, the app would feel too limited. By reusing the task creation page for editing, I made the workflow more flexible while keeping the design simple.

4. Technical Work Completed

From a technical point of view, I developed multiple content pages in .NET MAUI and connected them through navigation. I created a simple task model and a task service to hold study task data during runtime. The Daily Schedule page loads tasks by date, the Add Study Task page supports both creation and editing, and the Task Details page allows completion and deletion actions. I also improved the interface styling so the app looks cleaner and more suitable for a real user.

During this process I faced several coding issues, including XAML structure errors, page navigation problems, file locking during build, and data binding related problems. Solving these issues helped me understand how page structure, code-behind logic, and user interface design all need to work together in a mobile app.

5. Reflection

This stage of development taught me that a useful app is not created only by adding more features. It also depends on whether the common actions feel natural for the user. Small changes such as direct date selection, clearer completed-task feedback, and editable task details can greatly improve the experience. I now understand more clearly that app development must consider both technical implementation and user behaviour at the same time.

6. Next Steps

My next step is to continue improving the app so it feels even more complete. I plan to add better empty-state messages when no tasks exist for a selected date, improve validation for user input, and consider adding task filtering such as All, Pending, and Completed. If time allows, I would also like to improve reminder behaviour and local data storage so the app can better support real long-term use.
